(54) Title: MICROBIOLOGICALLY STABLE SAUCE EMULSION

(57) Abstract: A stable acidified, emulsified sauce containing preservatives, very high solids and salt is taught. The emulsion has selected emulsifiers and starches to result in good initial emulsification and good further dilution characteristics. The components of the sauce including solids, salt and preservatives, have been selected to achieve a 5 log microbiological kill on storage at ambient temperature without pasteurization and without adversely affecting the fresh flavor or the product.

MICROBIOLOGICALLY STABLE SAUCE EMULSION**Field of the Invention**

Generally the invention deals with a microbiologically stable liquid or paste sauce mix. The sauce mix does not have to be pasteurized.

Background of the Invention

Many products have been developed to assist in cooking meat or other protein. These include both dry mixes and liquid sauces.

U.S. 5,679,300 teaches a method and natural flavoring composition to impart deep-fried flavor without adding fat. 15 The composition is used to coat a product to be cooked.

U.S. 4,963,376 teaches a sauce for coating foods to give them a brown color and crisp texture when used with a microwave oven.

20

U.S. 5,008,124 teaches a dry mix which can be applied to moistened meat pieces. The mix then liquefies to produce a thickened gravy or sauce on cooking.

25 U.S. 5,424,088 discloses a specially prepared combined starch-natural gum composition. This composition is used as a thickening agent.

The art has not addressed the problem of a combined dry seasoning mix/liquid sauce mix which are designed to be 30 used together and to be complementary to each other. The

art usually deals separately with either selected dry mixes or sauces having no functional connection between the seasoning mix and the sauce. This separate treatment limits the convenience of the product and limits the flavor 5 nuances available. In addition, the less heat that is used in processing the products, the less flavor will be affected.

It is accordingly an object of this invention to 10 provide a sauce product which uses minimal or no heat in the process, yet is still microbiologically stable. This has been accomplished with the result that the sauce produces fresh taste on cook up of the end product.

15 Once the desirability of a two component sauce seasoning mix combination has been recognized, the next problem is how to manufacture it so that it is stable both physically and microbiologically and so that it provides the desired taste. Certain sauces must be liquid or fluid 20 because of the delicacy of the flavors involved. Drying the flavor and seasoning components of the sauce significantly alters their flavor profile and reduces the perception of freshness. In addition, certain, sometimes irreversible, physical changes take place on drying.

25 Further, the sauce should contain a highly concentrated emulsion which must be easy to dilute on use. The emulsion, which can be a liquid or a paste, must be stable enough for dilution without breaking and further, 30 the diluted emulsion itself must be stable enough to be

heated after dilution. In addition, the emulsion must be sufficiently freeze-thaw and heat stable to allow shipment and storing in normal commercial channels.

5 The emulsion must also be microbiologically stable, which in turn requires a pH of 4.5 or less since the emulsion, to be fluid, will have a water activity of about 0.7 to 0.85. The pH adjustment for microbiological stability in turn could easily render many versions of the
10 sauce too acidic for most tastes, especially dairy based sauces. To remedy this acidity a buffer is usually and preferably added to the seasoning mix to counteract the acidity of the sauce/diluted sauce emulsion. Stability of the emulsion is also important in the stored product
15 because if the emulsion breaks or separates, localized pockets of high water activity may result, which in turn could result in microbiological instability.

Summary of the Invention

20 It has now been found that an emulsified, acidified sauce mix with extremely high solids content and salt content can be prepared and used with the advantage of good microbiological stability. Of course, the sauce can also be used with selected seasoning mixes in the proper
25 circumstances. If properly processed, the sauce causes a 5 log decrease in organisms during a normal challenge test, thus essentially making pasteurization optional.

Detailed Description of the Invention

In a preferred embodiment of the cooking process using the combined sauce and seasoning mix, there will be a series of cooking steps. Preferably, the dry seasoning mix 5 is commingled with a protein source, such as chicken, to at least partially coat it and then the protein seasoning item is cooked. Chicken, or various other protein containing materials, may be cooked/roasted in the skillet or an oven dish after admixing with the dry mix, then a liquid is 10 added, which could be water, milk, wine or other liquid. Usually the sauce is added last after the liquid. Alternatively, the sauce can be diluted with the liquid and the whole then added to the cooked materials. Further cooking is then done to complete the dish. Carbohydrates, 15 such as pasta or rice and vegetables, may then be added during the final cooking steps or afterwards if desired.

The liquid sauce in order to be fluid has a certain amount of water employed Aw of 0.7 to 0.85 and thus must be 20 acidic and/or contain preservatives to prevent bacteriological growth. In order to counteract acidity, a buffer is employed in the dry mix to improve the palatability of the total mixture on cooking, especially when the sauces are dairy based.

25

Several dry seasoning mixes are disclosed herein as well as several combinations of shelf stable sauces for use with the dry seasoning mix and protein combinations.

The liquid/paste sauce mix is bacteriologically stable and indeed actually contributes to a five log bacterial kill in certain standard challenge tests. This stability is believed to be related to several individual parameters 5 or hurdles as follows: a preservative or mixture of preservatives; a low water content or low water activity; a very high solids/salt content and an acidulant. This hurdle technology is to prevent mold, yeast and other bacterial growth, the preservative system, the low water 10 content, the high solids and salt content and the acidulant all contribute to stability so there is no requirement to overload the food material with any single component. Since the sauce is highly concentrated, very high levels of salts can be employed because it is meant to be diluted in 15 use and so the high levels do not cause off-flavors.

Additionally, because of the very high solids level care must be taken to develop an appropriate emulsion. The acidulant provides the acid, which improves the microbial stability and helps to achieve a microbial kill in the 20 concentrated liquid sauce. This acidity, however, is controlled on cook-up to achieve a palatable taste in the final product.

One embodiment of the "hurdle" approach is described 25 in U.S. Patent 6,022,576 hereby incorporated by reference. The steps in the instant invention are somewhat similar and include using a pH of about 3.5 to 4.5; using high solids and high levels of salt with the pH adjustments; limiting the amount of water; using selected well known 30 preservatives such as nisin, natamycin, sorbic acid and

sorbates and benzoic acid and benzoates. Together these steps contribute to the antimicrobial effect and thus individually each is incrementally antimicrobially effective.

5

Each of these steps produces at least incremental and frequently synergistic antimicrobial effects. None of them however, substantially add or detract from the overall delicate flavor of the product. Rather, all of the steps 10 are taken to improve microbiological stability without negatively affecting the flavor. Thus, the incrementally antimicrobially effective amounts must take into account the flavor profile of the product.

15 As mentioned above, the buffering action of the spice, or herb, dry seasoning mix helps to control the acidity of the final product to improve palatability.

The dry spice seasoning mix may include herbs, spices 20 and other salts and several formulations have been disclosed below. These contain essentially dry components, but may also include some small amount of fat components as well as the buffer. The buffer can be any standard buffer, but is preferably sodium bicarbonate.

25

These other buffers that may be used include, for example, sodium citrate, sodium phosphate, sodium carbonate, sodium hexametaphosphate, potassium citrate, potassium phosphate, potassium carbonate, potassium 30 bicarbonate, potassium hexametaphosphate, sodium malate,

potassium malate, glucono-delta lactone, as well as buffering salts of any food acids and in some cases including calcium or magnesium salts where appropriate.

5 The amount of buffer will be about 5 to 25% of the spice mix, depending on the pH desired. Usually the pH desired in the final cooked up product will be about 4 to 7 so that the final food does not have a sour taste unless a sour taste, such as for Teriyaki versions, is desired.

10

In addition to the spice seasoning mix used to cook with the protein source, in the method of the invention a liquid is employed, which may be water or milk or wine or other liquid, depending on the type of end dish desired.

15 The amount of liquid varies depending on the liquidity desired by the consumer in the final dish.

The concentrate sauce, or stir sauce, can be fluid or paste and is a stabilized emulsion which contains about 20 20 to 40% water, about 15 to 40% oil, and about 25 to 65% solids, preferably about 50% to 65% solids, which may be powders or other particulate solids. This includes about 2 to 18% sodium chloride, preferably 8 to 12% sodium chloride. An emulsifier, which may be egg (as commonly used and also as described in U.S. Patent 4,034,124), or other emulsifiers, at a level of about 1 to 2% and Avicel 1340 at a level of 0.5 to 5%. Avicel contains carboxy methyl cellulose and sodium stearoyl lactylate (SSL) in ratios of about 70/30. The Avicel combination is 30 preferably used at about 0.5 to 1.0%. The sodium stearoyl

lactylate may be used at a level of 0.25 to 2%. Carboxy methyl cellulose may also be used at a level of 0.5 to 5%.

5 In addition xanthan gum is employed which protects the carboxy methyl cellulose from coalescing or precipitation and helps to stabilize the emulsion. This gum also contributes to viscosity so only small amounts are preferred. The xanthan may be used at a level of 0.1 to 10 about 0.25%.

A lipophilic starch is also used such as an N-CREAMER 46 or Purity gum 1773. These are used in amounts of 1 to 5%, preferably 1.5 to 2.5%, and provide dynamic shock 15 sensitive stabilization, eg. As shown by centrifugation. Further emulsifiers could be TWEEN 60, polysorbate 60 or any food grade emulsifier at a level of about 1 to 2% with an HLB of about 14 to 25. The emulsification incorporates the oil droplets into the water. The stabilizer then keeps 20 the emulsified droplets from coalescing or precipitating. In addition to the xanthan gum, other conventional gums may be used at similar levels such as propylene glycol alginate, pectin, guar, carageenan, gum arabic, gum tragacanth or indeed any salt resistant gum.

25

Purity gum 1773 is a modified food starch derived from waxy maize, having a unique emulsion stabilizing property. It is highly functional in emulsions of liquid foods containing fats and oils. This starch is used in the non 30 dairy systems. It is cold water soluble and has high

lipophilic properties resulting in excellent emulsion stability, as measured through centrifuge testing. In addition, Purity 1773 promotes Freeze-Thaw stability. In the system of the invention, this starch does not function 5 as a bulking agent and does not add substantial viscosity to the concentrated sauce. This product is described in Technical Service Bulletin CGB093 from National Starch and Chemical Company. Other modified corn starches may also be used in the same amounts.

10

Microcrystalline cellulose, sometimes called Cellulose Gel, is a naturally occurring cellulose that has been purified. The microcrystalline cellulose portion is coprocessed with an emulsifying agent called sodium 15 stearoyl lactylate. When combined together, Avicel 1340 has an excellent stabilizing capacity for thermal exposure throughout product life. The emulsion surpassed Hot Box testing at 110° F (1 month), and at 95° F (3 months). In addition, Avicel 1340 promotes Freeze-Thaw stability. 20 Avicel 1340 imparts minimal viscosity to the finished product.

Purity gum CSC is a high viscosity modified food starch, derived from waxy maize, that can be used in many 25 high pH food systems. It is a heat swelling and shear resistant starch, providing viscosity/thickness upon heat preparation. It is used in the invention in amounts of about 1 to 12%, preferably 2 to 7%. The starch remains inactive in the emulsified/concentrated sauce, but on 30 heating increases in viscosity. It has a smooth short

texture and will not set upon cooling. This product is described in Technical Service Bulletin 32087-311 from National Starch and Chemical Company.

5 N Creamer 46 is a modified food starch having an excellent emulsion stabilizing property. It is derived from waxy maize. This starch is used in the dairy systems of the invention only and provides a dairy flavor to the product. It is cold water soluble and has high lipophilic
10 properties resulting in excellent emulsion stability, as measured through centrifuge testing. In addition, N Creamer 46 promotes Freeze-Thaw stability. In the system of the invention, this starch does not function as a bulking agent and does not add substantial viscosity to the
15 concentrated sauce. This material is described in Technical Service Bulletin BHB041 from National Starch and Chemical Company.

S.D. Egg Yolk is a primary emulsifying agent
20 containing naturally occurring lecithins, having both hydrophilic and hydrophobic properties. The spray dried egg is used in the non-dairy systems of the invention and it is not enzyme modified.

25 Salted Liquid Egg containing lecithin and having both hydrophilic and hydrophobic properties is used. This liquid egg yolk has been modified with the enzyme lecithase. The use of liquid modified egg yolks in the dairy mixes of the invention results in sauce with greater

heat stability and provides a smoother and creamier finished product as described in U.S. Patent 4,034,124.

Xanthan Gum provides protection properties for Avicel 5 1340. A discussion of the physical and chemical properties may be found in Industrial Gums, R.L. Whistler, Ed., Academic Press, N.Y. (1973).

The water activity is preferably 0.7 to 0.85 and may 10 be as low as 0.5. The low end of the water activity (e.g. 0.5) has a high solids content and will make processing difficult and at the high end of water activity, it is difficult to get a microbial kill since heating is not required.

15

The sauce is preferably prepared using a two step process. Initially, the Avicel is added to water, followed by mixing in a high shear vessel. Xanthan and starch can be added using an oil slurry to protect the cellulose gel 20 structure. The following are then incorporated into the mixing vessel: preservatives, egg yolk, salt, flavors, onion, garlic, oil, spices, acids, cheese powders/pastes and the like (as appropriate dependent on the sauce system). After each ingredient is added, the appropriate 25 mix time is given to incorporate and hydrate the ingredients into a homogeneous mixture. The resultant mixture is a pre-emulsion of the final sauce.

The pre-emulsion is then passed through a vacuum 30 system, processed through a high shear device, for example

a high pressure homogenizer, a rotor-stator mixer, or a colloid mill. Once homogenized, excess heat is removed through a heat exchanger to assure that the emulsion remains stable. It is then held in a mixing vessel under 5 light agitation where particulates may be added to the final sauce. Once quality parameters are checked, it is ready to be packaged.

It has been found that the emulsion does have 10 microbial kill and thus pasteurization is optional. Consequently, since heating is not required, this improves the flavored freshness of the product. The preservatives employed are preferably sodium benzoate and/or sodium sorbate but nisin, natamycin and other microbiological 15 preservatives may also be used, from about 3000ppm to about 5000ppm in the emulsion and down to 50ppm to 1200ppm after dilution. The pH employed is 4.5 or lower or even 3.5 or 3.0 depending on taste. It must be below about 4.6 which is the U.S. Code of Federal Regulations limit for low acid 20 food. Depending on the pH and flavor desired in the sauce, the buffer in the seasoning mix must be adjusted to control the pH for selected taste.

A typical cook up method for the combined seasoning 25 mix and sauce mix is to add oil to a small pan, heat the pan and add the protein, for example chicken pieces. The dry seasoning mix may then be sprinkled on the cooking protein and the mix then seared preferably for four to five minutes on high heat. After the protein is cooked, liquid 30 is added to the protein in the pan, usually three cups,

which may be water, milk, wine and the like depending on taste. The sauce is then preferably added to the pan and the whole mixture heated. Optionally, pasta or rice or other carbohydrates and vegetables, either frozen or fresh, 5 are also added. The entire mixture may then be boiled to cook the optional carbohydrate or vegetable if used. The liquid and sauce could be pre-mixed before adding to the protein if desired.

10 As used herein, the word "comprising" is intended to mean including but not necessarily "consisting essentially of", "consisting of" or "composed of". In other words, "comprising" the listed steps or options need not be exhaustive.

15

Except in the examples, or where otherwise explicitly indicated, all numbers in this description indicating amounts of material or conditions of reaction, physical properties of materials and/or use are to be understood as 20 modified by the word "about." All amounts are by weight of the composition, unless otherwise specified.

Centrifuge Test

This test is used to establish emulsion stability. A 25 100 gram sample is placed in a centrifuge bottle and spun for twenty minutes at about 4,000 times gravity. Any oil separation is weighed. This test is then repeated on the same sample four times for the same amount of time for each repeat run. The oil separating out after each run is 30 collected and weighed. If the total amount of oil

separating out after five runs is 25% or less of the total oil in the sample, the emulsion is stable. The inventive emulsion thus has a centrifuge stability of about 25% or better. The less oil that separates out establishes a better and more stable emulsion.

The invention is illustrated by the following Examples.

5 **Example IX**

The liquid or paste sauces were formulated for ambient shelf stability (about 73° F) to be packaged with or without atmosphere control, for example, nitrogen flush to remove oxygen. The product required a fresher taste unaffected by heat. Therefore, products were formulated to address microbiological shelf stability, as well as, pathogen reduction or survival. The objective was to formulate a product that would not support the growth of spoilage microorganisms and in the absence of pasteurization, would also deliver a 5-log reduction of key recognized food-borne pathogens that would have normally been targeted if heat or other process were applied.

The dynamics of bacterial death is typically logarithmic, with each 10% sub-population demonstrating increased levels of resistance. The 5-log reduction is a fairly conservative approach to ensure safety. It 5 anticipates a relatively high contamination level and addresses the resistant sub-populations. Sauce formulation constituents were boosted to lower the pH to mildly acidify the sauces and lower Aw (Water Activity). Included were sorbic acid and sodium benzoate preservatives.

10 Typically, these preservatives are used in foods to prevent spoilage or enhance shelf life. However, these have not been applied to achieve a 5-log reduction of key vegetative pathogens in place of other processing methods.

15 The pathogens used in the challenge studies were *E.coli* 0157:H7, *Salmonella* spp., and *Listeria monocytogenes*.

The objective was to evaluate the survival of *E.coli* 20 0157:H7, *Salmonella* spp., and *L.monocytogenes* in different flavor varieties of sauces. The sauces tested were very similar to the Examples herein: Three Cheese Alfredo Sauce (Example III), Teriyaki Sauce (Example VI), Savory Chicken Sauce (Example IV), Spanish Style Sauce (Example V), 25 Cheddar Sauce (Example VIII), and Lemon Garlic Sauce (Example VII) for Chicken. The formulations tested were in some respects different from those listed under examples III to VIII inclusive. Specifically, in that the pH was varied some and the water activity was also varied.

Methodology

The strain sources were from the following collection:
E.coli 0157:H7 (35150; 48895; 43889; 380-94 FSIS Salami;
JIT Box #145).
5 *Salmonella* spp. (4031; 8326; 4931; 14028; *S.agona*;
S.newport).
Listeria monocytogenes (Lm 19111; Lm8; Lm10 Jalisco; CA-2;
Lm 16 CA-1; Lm Scott A; Lm V7).

10 The bacteria were grown in BHI with 1% Glucose at 35°C
for 2 days. The tests included at least 4 different
strains for each. The strains were pooled into three
separate tubes to attain a target population of 10^8 -
 10^9 /ml for each of the three pathogens. Sauce was
15 aseptically added to individual sterile Whirl Pak pouches
and weighed to contain 11 - 12 grams of sauce each. These
sauce packets were inoculated using 0.1ml of the individual
bacterial pools, and mixed well by massaging the pouch
exterior. Only one genus type pathogen was added to
20 individual packets to avoid interaction. Enough packets
were prepared to allow for daily destructive sampling and
testing for up to 10 days. Uninoculated controls were also
tested at the beginning, middle, and end of the test
period.

25 Inoculated sauce was maintained in a controlled
temperature environment to simulate ambient at 23°C.
Packets were analyzed destructively each day.
Butterfield's Buffers (99ml) were used to prepare 1:10
30 dilutions. About 10 ml of buffer was added to each pouch

to dilute the sauce and facilitate complete removal of sauce out of the pouch and into the buffer dilution blank.

E.coli 0157:H7 was enumerated using both Sorbitol MacConkey Agar (CTSMAC) and *E.coli* 3MpetriFilm at 35°C(2 -3 days). *L.monocytogenes* was enumerated using both Listeria Selective Agar (MOX) with added colistin (10mg/L) and moxalactam (15mg/L), and APC 3Mpetrifilm at 30°C(2 -3 days). *Salmonella spp.* was enumerated on Hektoen Enteric Agar and Xylose Lysine Desoxycholate Agar at 35°C(2 -3 days).

When sauce packets reached 4 days at 23°C ambient, enrichment was performed in addition to direct enumeration. This enabled determination of survival (presence or absence) when counts were reduced below 10 cfu per gram. In place of Butterfield's Buffer, Tryptone Soy Broth (99ml) supplemented with yeast extract was used to enrich sauces inoculated with *E.coli* 0157:H7 and sauces inoculated with *Salmonella*. Enrichment broths were incubated at 35°C for 24 hours. *E.coli* TSBYE were spread plated onto SMAC (CTSMAC). *Salmonella* TSBYE were transferred (1.0ml) to tubes of Tetrathionate Broth and Selenite Cystine Broth for 24 hours at 35°C. These were subsequently streaked onto HE and XLD using 3mm loops and incubated for 24 hours at 35°C. For Listeria, enrichment was also performed in addition to direct enumeration. In place of Butterfield's Buffer, UVM Broth (99ml) with added naladixic acid (20 mg/L) and acriflavine hydrochloride (25mg/L) was used to enrich the sauce for 24 hours at 30°C. Secondary

enrichment was performed using Fraser Broth for 24 hours and 48 hours at 30°C, with streaking onto MOX plates immediately at these times, and incubating at 30°C for 2 days.

5

The data for these challenge studies have been graphed.
~~NOT TO BE TAKEN INTO CONSIDERATION FOR THE PURPOSE OF THIS INTERNATIONAL APPLICATION~~ [and included in figures A1-A18 (inclusive)]. These graphs have been made on logarithmic scales, and demonstrate the log reductions taking population levels from 6 and 7 log levels down to less than 1, followed by complete die off, achieving a minimum 5 log reduction. Significant reduction was achieved within 48 hours at ambient (23°C). Whereas, at refrigerated temperatures (10° C) the effect was less. Due to potential inhibition of the sauce constituents (acids and salts) on bacterial growth within enumeration medium, counts may not be reliable on low dilution plates (10^{-1} plates). Therefore, enrichments were performed to overcome the inhibition and identify presence or absence to determine survival and time of complete die off. The results show the minimum 5 log reduction was achieved with 2 days storage at ambient and greater than 5 logs within 5 days maximum. When sauce samples were chilled at 10°C (50°F), survival was extended (see Alfredo sauce results). Good enumeration was achieved on plates with dilutions $>10^{-1}$. Particularly good counts (consistently higher) were attained with *E.coli* 3MPetriFilm versus SMAC, and with APC 3MPetriFilm versus MOX. However, on 10^{-1} . Plates, these were very unreliable showing clear zones of inhibition, and much better data was attained using SMAC and MOX in place of PetriFilm.

Specific formulation constituents were boosted to achieve product stability and deliver a minimum 5-log reduction of known vegetative pathogens. These 5 constituents include sorbic acid and sodium benzoate. Typically, these preservatives are used in foods to prevent spoilage or enhance shelf life. However, these have not been applied to achieve a 5 log reduction of key vegetative pathogens in place of other processing methods, such as: 10 heat or thermal processing; filtration (reverse osmosis); high pressure processing; microwaves, UV, X-ray, and gamma irradiation, or combinations of the above. The effect on pathogen survival and 5-log reduction is promoted using other sauce parameters, such as, Aw and pH (such as, using 15 salt and added acidulants, for example, lactic acid and phosphoric acid, and with the addition of calcium disodium EDTA).

Figures 1, 2 and 3 represent Salmonella, E Coli and 20 Listeria respectively with a formulation similar to Example III and 0.15% sorbic acid and 0.3% benzoate.

Figures 4, 5 and 6 represent Salmonella, E Coli and Listeria respectively with a formulation similar to Example 25 IV and 0.2% sorbic acid and 0.1% benzoate.

Figures 7, 8 and 9 represent Salmonella, E Coli and Listeria respectively with a formulation similar to Example V and with a formulation of 0.22% sorbic acid and 0.1% 30 benzoate.

Figures 10, 11 and 12 represent Salmonella, E Coli and Listeria in a formulation similar to Example VI with 0.2% sorbic acid and 0.1% benzoate.

5

Figures 13, 14 and 15 represent Salmonella, E Coli and Listeria in a formulation similar to Example VII with 0.2% sorbic acid and 0.1% benzoate.

10 Figures 16, 17 and 18 represent Salmonella, E Coli and Listeria in a formulation similar to Example VIII with 0.15% sorbic acid and 0.3% benzoate.

It is understood that the examples and embodiments
15 described herein are for illustrative purposes only and
that various modifications or changes in the light thereof
will be suggested to persons skilled in the art and are to
be included within the spirit and purview of this
application and the scope of the appended claims.

20

WHAT IS CLAIMED IS:

1. A stable acidified emulsion having a centrifuge stability of 25% and being capable of a 5 log microbial kill without pasteurization comprising:
 - about 20% to 40% water;
 - about 15% to 40% oil;
 - about 25% to 65% solids, said solids including about 2% to 18% sodium chloride;
 - about 1% to 2% of an emulsifier;
 - about 3000 ppm to about 5000 ppm of a preservative;
 - about 1% to 5% of a lipophilic starch;
 - about 0.5% to 5% of microcrystalline cellulose;
 - about 0.25% to 2% of sodium stearoyl lactylate;
 - a sufficient amount of an acidulant to result in a pH of about 3.0 to 4.6 in said stabilized emulsion;
 - about 0.1% to 0.25% of an edible gum;
 - about 1% to 12% of a heat swelling starch

2. An emulsion as defined in claim 1 wherein said sodium chloride is present in an amount of about 8% to 12%.
3. An emulsion as defined in claim 1 wherein said emulsifier has an HLB of about 14 to 25.
4. An emulsion as defined in claim 3 wherein said emulsifier is egg or enzyme treated egg.
5. An emulsion as defined in claim 1 wherein said lipophilic starch is derived from waxy maize and is cold water soluble.
6. An emulsion as defined in claim 1 wherein said acidulant is present in an amount sufficient to yield a pH of about 3.5 to 4.5.
7. An emulsion as defined in claim 1 wherein said gum is selected from the group consisting of xanthan, carageenan, pectin, guar, gum arabic, gum tragacanth and propylene glycol alginate.
